

Exercise 3.8 (*)

Let $h : \mathbb{R} \rightarrow \mathbb{R}$ be the 1-periodic function satisfying $h(x) = |x|$ for $x \in [-\frac{1}{2}, \frac{1}{2}]$ (and $h(x+1) = h(x)$). Define the Takagi function

$$T(x) = \sum_{i=0}^{\infty} \frac{1}{2^i} h(2^i x).$$

- (a) *Sketch h .* On $[-\frac{1}{2}, \frac{1}{2}]$ it is the V-shape $|x|$ (cusp at 0), extended periodically with period 1. Equivalently,

$$h(x) = \text{dist}(x, \mathbb{Z}) = \min_{k \in \mathbb{Z}} |x - k|,$$

so $0 \leq h(x) \leq \frac{1}{2}$, attaining 0 at integers and $\frac{1}{2}$ at half-integers.

- (b) *Uniform continuity and differentiability.* Since $x \mapsto \text{dist}(x, \mathbb{Z})$ is 1-Lipschitz, h is uniformly continuous on $\mathbb{R}$. On each interval $(k, k + \frac{1}{2})$ and $(k - \frac{1}{2}, k)$ the function is affine with slope -1 or $+1$, hence differentiable there. It fails to be differentiable precisely at points congruent to 0 or $\frac{1}{2}$ modulo 1, i.e. at those x with $2x \in \mathbb{Z}$. Thus h is differentiable at every x with $2x \notin \mathbb{Z}$.

- (c) *Uniform convergence of the series and uniform continuity of T .* Since $0 \leq h \leq \frac{1}{2}$,

$$\left| \frac{1}{2^i} h(2^i x) \right| \leq \frac{1}{2^{i+1}} \quad (\forall x \in \mathbb{R}),$$

and $\sum_{i=0}^{\infty} 2^{-(i+1)} < \infty$. By the Weierstrass M -test, the series converges uniformly on $\mathbb{R}$ to a continuous function T . Each summand $x \mapsto 2^{-i} h(2^i x)$ is uniformly continuous (indeed 1-Lipschitz), hence T , being a uniform limit of uniformly continuous functions, is uniformly continuous on $\mathbb{R}$.

- (d) Let $x \in \mathbb{R}$. There exist unique u_n, v_n such that

- (i) $2^n u_n, 2^n v_n \in \mathbb{Z}$,
- (ii) $v_n - u_n = 2^{-n}$,
- (iii) $u_n \leq x < v_n$.

Solution. Take $u_n = \frac{\lfloor 2^n x \rfloor}{2^n}$ and $v_n = u_n + 2^{-n}$. Then (i)–(iii) hold. Uniqueness: if $u'_n \leq x < v'_n$ with (i)–(ii), then $2^n u'_n \leq 2^n x < 2^n v'_n$ and $2^n v'_n - 2^n u'_n = 1$, so $2^n u'_n = \lfloor 2^n x \rfloor = 2^n u_n$, hence $u'_n = u_n$ and $v'_n = v_n$.

- (e) For $i \geq 0$ set $h_i(x) = 2^{-i} h(2^i x)$. Show that:

- (i) $h_i(u_n) = h_i(v_n) = 0$ for $i \geq n$.
- (ii) $\frac{h_i(v_n) - h_i(u_n)}{v_n - u_n} = \pm 1$ for $i < n$.

Solution. (i) Since $2^n u_n, 2^n v_n \in \mathbb{Z}$, for $i \geq n$ also $2^i u_n, 2^i v_n \in \mathbb{Z}$, hence $h(2^i u_n) = h(2^i v_n) = 0$.

(ii) The map $x \mapsto 2^i x$ sends $[u_n, v_n]$ onto the interval $[\frac{K}{2^{n-i}}, \frac{K+1}{2^{n-i}}]$ where $K = \lfloor 2^n x \rfloor$. Its length is $2^i(v_n - u_n) = 2^{-(n-i)} \leq \frac{1}{2}$, so it contains no half-integer. Hence h is affine with slope ± 1 on this interval, and therefore

$$\frac{h_i(v_n) - h_i(u_n)}{v_n - u_n} = \frac{2^{-i}(h(2^i v_n) - h(2^i u_n))}{2^{-n}} = 2^{n-i} \cdot 2^{-i} \cdot (\pm 2^{-(n-i)}) = \pm 1.$$

(f) *Conclude that*

$$\frac{T(v_n) - T(u_n)}{v_n - u_n} = \sum_{i=0}^{n-1} \frac{h_i(v_n) - h_i(u_n)}{v_n - u_n},$$

and that the sum on the right does not converge as $n \rightarrow \infty$.

Solution. Since $h_i(u_n) = h_i(v_n) = 0$ for $i \geq n$,

$$T(v_n) - T(u_n) = \sum_{i=0}^{\infty} (h_i(v_n) - h_i(u_n)) = \sum_{i=0}^{n-1} (h_i(v_n) - h_i(u_n)).$$

Divide by $v_n - u_n$ to get the displayed identity. By (e)(ii), each term of the sum equals ± 1 , so the sequence of partial sums cannot converge (successive differences are $\pm 1 \not\rightarrow 0$). Hence the right-hand side does not converge as $n \rightarrow \infty$. In particular, T is nowhere differentiable.
